# 34 Line impedance, generalized reflection coefficient, Smith Chart 

- Consider a TL of an arbitrary length $l$ terminated by an arbitrary load

$$
Z_{L}=R_{L}+j X_{L} .
$$

as depicted in the margin.

Voltage and current phasors are known to vary on the line as

$$
V(d)=V^{+} e^{j \beta d}+V^{-} e^{-j \beta d} \quad \text { and } \quad I(d)=\frac{V^{+} e^{j \beta d}-V^{-} e^{-j \beta d}}{Z_{o}} .
$$

In this lecture we will develop the general analysis tools needed to determine the unknowns of these phasors, namely $V^{+}$and $V^{-}$, in terms of source circuit specifications.

- Our analysis starts at the load end of the TL where $V(0)$ and $I(0)$ stand for the load voltage and current, obeying Ohm's law

$$
V(0)=Z_{L} I(0) .
$$

Hence, using $V(0)$ and $I(0)$ from above, we have

$$
V^{+}+V^{-}=Z_{L} \frac{V^{+}-V^{-}}{Z_{o}} \Rightarrow V^{-}=\frac{Z_{L}-Z_{o}}{Z_{L}+Z_{o}} V^{+} .
$$

- Define a load reflection coefficient

$$
\Gamma_{L} \equiv \frac{Z_{L}-Z_{o}}{Z_{L}+Z_{o}}
$$

and re-write the voltage and current phasors as

$$
V(d)=V^{+} e^{j \beta d}\left[1+\Gamma_{L} e^{-j 2 \beta d}\right] \quad \text { and } \quad I(d)=\frac{V^{+} e^{j \beta d}\left[1-\Gamma_{L} e^{-j 2 \beta d}\right]}{Z_{o}}
$$

- Define a generalized reflection coefficient

$$
\Gamma(d) \equiv \Gamma_{L} e^{-j 2 \beta d}
$$

and re-write the voltage and current phasors as

$$
V(d)=V^{+} e^{j \beta d}[1+\Gamma(d)] \quad \text { and } \quad I(d)=\frac{V^{+} e^{j \beta d}[1-\Gamma(d)]}{Z_{o}} .
$$

- Line impedance is then defined as

$$
Z(d)=\frac{V(d)}{I(d)}=Z_{o} \frac{1+\Gamma(d)}{1-\Gamma(d)}
$$

for all values of $d$ on the line extending from the load point $d=0$ all the way to the input port at $d=l$.

With the dependence on $d$ of $Z(d)$ as well as $\Gamma(d)$ tacitly implied, we can re-write this important relation and its inverse as

$$
\frac{Z}{Z_{o}}=\frac{1+\Gamma}{1-\Gamma} \quad \Leftrightarrow \quad \Gamma=\frac{Z-Z_{o}}{Z+Z_{o}} .
$$

"Load reflection coefficient" is a well justified name for $\Gamma_{L}$ since the forward traveling wave with phasor $V^{+} e^{j \beta d}$ gets reflected from the load.

The term "generalized reflection coefficient" is also well justified even if there is no reflection taking place at arbitrary $d$ - the reason is, if the line were cut at location $d$ and the stub with the load were replaced by a lumped load having a reflection coefficient equal to $\Gamma(d)$, then there would be no modification of the voltage and current variations on the line towards the generator.

Each location $d$ on the line has an impedance $Z$ and a reflection coefficient $\Gamma$ linked by these equations.

Properties of $Z(d)=R(d)+j X(d)$ and $\Gamma(d)=\Gamma_{L} e^{-j 2 \beta d}$ linked by the relations

$$
\frac{Z}{Z_{o}}=\frac{1+\Gamma}{1-\Gamma} \quad \Leftrightarrow \quad \Gamma=\frac{Z-Z_{o}}{Z+Z_{o}}:
$$

1. For real valued $Z_{o}$ and $R(d) \geq 0,|\Gamma(d)| \leq 1$ :

## Verification:

$$
|\Gamma|=\frac{\left|Z-Z_{o}\right|}{\left|Z+Z_{o}\right|}=\frac{\left|\left(R-Z_{o}\right)+j X\right|}{\left|\left(R+Z_{o}\right)+j X\right|}=\frac{\sqrt{\left(R-Z_{o}\right)^{2}+X^{2}}}{\sqrt{\left(R+Z_{o}\right)^{2}+X^{2}}} .
$$

Since with $R \geq 0$

$$
\sqrt{\left(R-Z_{o}\right)^{2}+X^{2}} \leq \sqrt{\left(R+Z_{o}\right)^{2}+X^{2}} \Rightarrow|\Gamma| \leq 1 .
$$

2. Since

$$
|\Gamma|=\left|\Gamma_{L}\right| \quad \text { and } \quad \angle \Gamma(d)=\angle \Gamma_{L}-2 \beta d
$$

property (1) implies that $\Gamma(d)$ is a complex number which is constrained to be on or within the unit-circle on the complex plane.
3. Relationships

$$
\frac{Z}{Z_{o}}=\frac{1+\Gamma}{1-\Gamma} \quad \Leftrightarrow \quad \Gamma=\frac{Z-Z_{o}}{Z+Z_{o}}
$$

between $\Gamma$ and $Z$ are known as bilinear transformations - here the term bilinear refers to the numerator as well as the denominator of these transformations being linear in the variable being transformed (from right to left).

Bilinear (or Möbius) transformations are known to have the general property of mapping straight lines into circles on the complex number plane.

- Bilinear transformations between

$$
\Gamma \equiv \Gamma_{r}+j \Gamma_{i} \equiv\left(\Gamma_{r}, \Gamma_{i}\right)
$$

and

$$
\frac{Z}{Z_{o}} \equiv z \equiv r+j x
$$

known as normalized impedance, lead to an ingenious graphical aid known as the Smith Chart.

- On a Smith Chart (SC), straight lines on the right hand side of the complex number plane (see margin), represented by

$$
r=\text { const. and } \quad x=\text { const. },
$$

are mapped onto circular loci of

$$
\left(\Gamma_{r}, \Gamma_{i}\right)=\Gamma=\frac{Z-Z_{o}}{Z+Z_{o}}=\frac{z-1}{z+1}
$$

occupying the region of the plane bordered by the unit circle.
Circles corresponding to $z=$ const. $+j x$ and $z=r+j$ const. constitute a griding of the unit circle and its interior. By means of this grid, the normalized impedance $z$ corresponding to every possible $\Gamma$ can be directly read off the SC.

- SC can be constructed by first noting that

$$
\Gamma=\frac{z-1}{z+1}=\frac{r+j x-1}{r+j x+1}=\frac{[(r-1)+j x][(r+1)-j x]}{(r+1)^{2}+x^{2}}=\frac{\left(r^{2}+x^{2}-1\right)+j 2 x}{(r+1)^{2}+x^{2}} \equiv \Gamma_{r}+j \Gamma_{i} ;
$$

thus

$$
\Gamma_{r}=\frac{\left(r^{2}+x^{2}-1\right)}{(r+1)^{2}+x^{2}} \text { and } \Gamma_{i}=\frac{2 x}{(r+1)^{2}+x^{2}}
$$

and by direct substitution we can verify the following equations

$$
\left(\Gamma_{r}-\frac{r}{r+1}\right)^{2}+\Gamma_{i}^{2}=\left(\frac{1}{r+1}\right)^{2} \text { and }\left(\Gamma_{r}-1\right)^{2}+\left(\Gamma_{i}-\frac{1}{x}\right)^{2}=\left(\frac{1}{x}\right)^{2}
$$

describing $r$ and $x$ dependent circles, respectively, on complex plane constituting the grid lines of the SC.

- Typical SC usage:

1. Locate and mark $z(0)$ - normalized load impedance - on the SC, which places you at a distance $|\Gamma(0)|=\left|\Gamma_{L}\right|$ from the origin of the complex plane (and the SC), at an angle of $\theta=\angle \Gamma(0)$.
2. Draw a constant $|\Gamma|=\left|\Gamma_{L}\right|$ circle with a compass going through point $z(0)$ on the SC (the read circle in the margin). Rotate clockwise on the circle by an angle of

$$
2 \beta d=\frac{4 \pi}{\lambda} d \mathrm{rad}=\frac{d}{\lambda / 2} 360^{\circ}
$$

to land on $z(d)$ that can be read off using the SC gridding.

- Rotation by an angle of $2 \beta d$ amounts to rotation by full circle for $d=\frac{\lambda}{2}$,
rotation by half circle for $d=\frac{\lambda}{4}$,
rotation by quarter circle for $d=\frac{\lambda}{8}$, etc.

3. Also,

$$
y(d) \equiv \frac{1}{z(d)}
$$

which is the normalized line admittance is located on the SC on the constant $|\Gamma|=\left|\Gamma_{L}\right|$ circle across the point corresponding to $z(d)$.

Verification: Since

$$
z=\frac{1+\Gamma}{1-\Gamma} \Rightarrow y=\frac{1}{z}=\frac{1-\Gamma}{1+\Gamma}=\frac{1+(-\Gamma)}{1-(-\Gamma)} ;
$$

hence whereas $z$ is the transform of $\Gamma, y$ is the transform of $-\Gamma$, having the same magnitude as $\Gamma$ but an angle off by $\pm 180^{\circ}$.

- Therefore, "reflect" on the SC across the origin to jump from $z(d)$ to $y(d)$ if you need the value of the normalized admittance.

Our first SC example is given next.

Example 1: A transmission line is terminated by an inductive load of

$$
Z_{L}=50+j 100 \Omega .
$$

Determine the input impedance $Z_{i n}=Z(l)$ of the line at a distance

$$
d=l=\frac{\lambda}{8}
$$

if the characteristic impedance of the line is $Z_{o}=50 \Omega$. Also determine the normalized input admittance $y(l)$.

Solution: The normalized load impedance is

$$
z(0)=\frac{Z_{L}}{Z_{o}}=\frac{50+j 100}{50}=1+j 2 .
$$

Enter $z(0)$ on the SC and then rotate clockwise by $\frac{\lambda}{8} \Leftrightarrow$ (quarter circle) to obtain the normalized input impedance

$$
z(l)=1-j 2,
$$

and the normalized input admittance

$$
y(l)=0.2+j 0.4
$$

right across $z(l)$. The input impedance is

$$
Z_{i n}=Z_{o} z(l)=50(1-j 2)=50-j 100 \Omega .
$$

Blow up of the SC's used in Example 1:
(a) At load point

(b) at input point

- A SmithChartTool linked from the class calendar (a javascript utility that requires a Safari or Firefox browser to work properly) marks and prints $z(d)$ in red and $y(d)$ in magenta across from $z(d)$ on the constant- $\left|\Gamma_{L}\right|$ circle (shown in red) as in the above examples. Also
- printed in black is the real valued normalized impedance $z\left(d_{\text {max }}\right)$ discussed in the upcoming lectures (also known as VSWR).
- also printed in red is $\left|\Gamma_{L}\right| \angle \Gamma(d)$ where the second entry is expressed in terms of an equivalent $\frac{d}{\lambda}$ such that $\frac{d}{\lambda}=0.5$ corresponds to an angle of $360^{\circ}$. This way of referring to $\angle \Gamma(d)$ will be convenient in many SC applications that we will see.
